

Forms and Inputs

Where we stopped two weeks ago

- We created a 'product' page that shows one product
- It has a 'Add to cart' button that will be disabled once the stock level is zero
- It has a 'Checkout' button that switch the view between the product and checkout page
- So far the 'checkout' page is still empty

Vue.js Pet Depot

0  Checkout

Cat Food, 25lb bag

A 25 pound bag of *irresistible*, organic goodness for your cat.

Price: 2000

Add to cart

This week

- We will create the 'checkout page' similar to this
- On which user can enter their details
- The details will be checked to ensure they are correct
 - For example, only numbers are entered for phone number

Outline

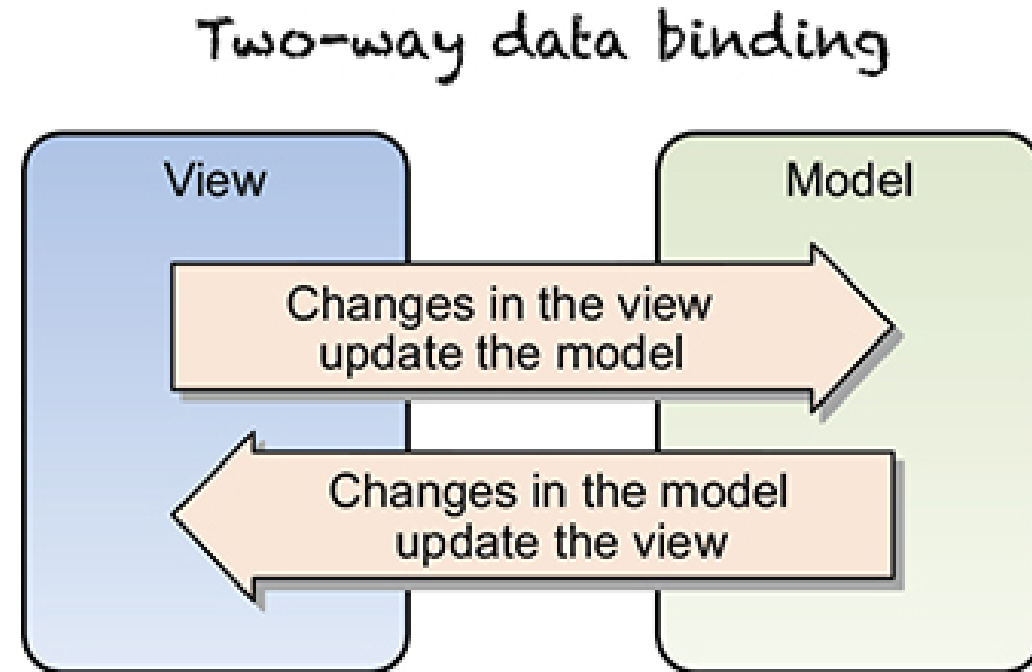

- Binding values with `v-model`
- Binding values with `v-bind` and `v-for`
- Modifiers

v-model

- We need to get the user details from the html form
- Previously we do this with `document.getElementById('#inputFieldID').value`
- Vue.js has a directive called `v-model` to make this easier
- Work with all form inputs: text boxes, text areas, check boxes, radio buttons, and dropdown menu.

v-model binding is two way

- When new value is entered in the form, the value of the bound vue property also changes
- When the value of the vue property changes, so does the value in the html input element
- **v-once** can be used for one-way binding

`v-model` vs. `v-bind`

- The `v-model` directive is used mainly for input and form binding.
 - We'll use the `v-model` here to bind text inputs on the checkout page.
- The `v-bind` directive is mostly used to bind HTML attributes.
 - We can use `v-bind` on an `src` attribute on an `` tag, or
 - bind it to the class attribute on a `<div>` tag.
- Both are useful, yet they're used in different situations.

An example

- The `input` is the form field that will be linked
- The `order.lastName` is the Vue `data`` property that the form field will link to

v-model directive

```
<input v-model="order.lastName"/>
```

tag name

two-way data bound object

The diagram shows the code snippet `<input v-model="order.lastName"/>`. A bracket above the `v-model="order.lastName"` is labeled "v-model directive". A line pointing to the `<input` is labeled "tag name". A bracket below the `order.lastName` is labeled "two-way data bound object".

Binding the name

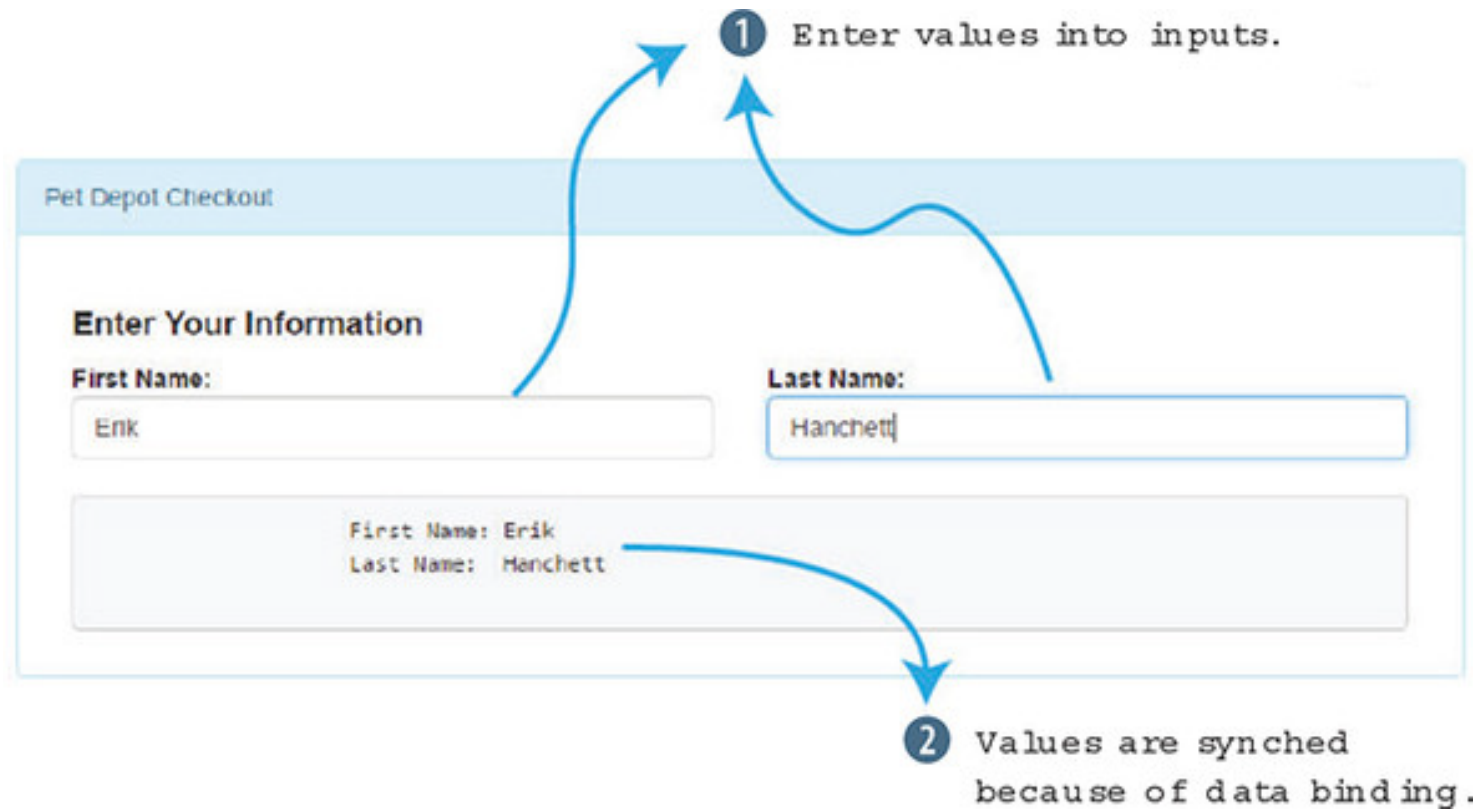

```
<h2>Checkout</h2>
<p>
  <strong>First Name:</strong>
  <!-- This input field is bound to 'firstName' in the 'order' object -->
  <input v-model="order.firstName"/>
</p>
<p>
  <strong>Last Name:</strong>
  <!-- This input field is bound to 'lastName' in the 'order' object -->
  <input v-model="order.lastName"/>
</p>
<h2>Order Information</h2>
<p>First Name: {{order.firstName}}</p>
<p>Last Name: {{order.lastName}}</p>
```

Storing the 'name' in data

```
data: {  
  sitename: 'Vue.js Pet Depot',  
  showProduct: true,  
  order: {  
    firstName: '',  
    lastName: ''  
  },  
  ...  
}
```

Realtime update

As the user types in the name, it shows up in the pane below in realtime

Adding other fields

```
<p><strong>Address:</strong> <input v-model="order.address"/></p>

<p><strong>City:</strong> <input v-model="order.city"/></p>

<p>
  <strong>State:</strong>
  <select v-model="order.state">
    <option disabled value="">State</option>
    <option>AL</option>
    <option>AR</option>
    <option>CA</option>
    <option>NV</option>
  </select>
</p>

<p><strong>Zip/Postal Code:</strong> <input v-model="order.zip"/></p>
```

Checkout

Displaying all the fields

```
<h2>Order Information</h2>
<p>First Name: {{order.firstName}}</p>
<p>Last Name: {{order.lastName}}</p>
<p>Address: {{order.address}}</p>
<p>City: {{order.city}}</p>
<p>Zip: {{order.zip}}</p>
<p>State: {{order.state}}</p>
```

- Note that we haven't add the new fields to the `data` yet
- However, they can already be used, such as `Zip: {{order.zip}}`
- Because Vue can **implicitly** add new properties
- However, it is a good practice to do this explicitly

Adding the fields to **order** object

```
data: {  
  sitename: "Vue.js Pet Depot",  
  showProduct: true,  
  order: {  
    firstName: '',  
    lastName: '',  
    address: '',  
    city: '',  
    zip: '',  
    state: ''  
  },  
}
```

Checkbox and radio button

- Checkbox: allow customer to ship as a gift
- Radio button: ship to 'home' or 'business' address
 - We must set the `v-model` in both check boxes to the same value

```
<p><input type="checkbox" id="gift" value="true" v-model="order.gift">  
<label for="gift">Ship As Gift?</label></p>  
  
<p><input type="radio" id="home" value="Home" v-model="order.method">  
<label for="home">Home</label>  
<input type="radio" id="business" value="Business" v-model="order.method">  
<label for="business">Business</label></p>
```

Setting the default value

- You can set the default value for the input field using the property in `data`
- Below we set the default address to 'Home' and default gift option as 'false'

```
data: {  
  sitename: "Vue.js Pet Depot",  
  showProduct: true,  
  order: {  
    ...  
    method: 'Home',  
    gift: false  
  },  
}
```

Gift? false

Method: Home

The 'place order' button

- Add a 'Place order' button with `v-on :`
 - `<button v-on:click="submitForm">Place Order</button>`
- Add the `submitForm` function to the Vue method
 - `submitForm() {alert('Order submitted!')}`
 - For now this just displays an alert. Later we will add more functions such as user input validation.

The screenshot shows a web application interface. At the top left, there is a logo that says "Vue.js". To its right, a notification box displays "127.0.0.1:5500 says" and "Order submitted!" with an "OK" button. Below the notification, there is a "Checkout" section. It includes a shopping cart icon with "0" items, followed by input fields for "First Name:", "Last Name:", "Address:", "City:", "State:" (a dropdown menu), and "Zip / Postal Code:". There are also checkboxes for "Ship As Gift?" and radio buttons for "Home" (selected) and "Business". Below this is an "Order Information" section with labels for "First Name:", "Last Name:", "Address:", "City:", "Zip:", "State:", "Gift? false", and "Method: Home". At the bottom of the form is a "Place Order" button.

Outline

- Binding values with `v-model`
- **Binding values with `v-bind` and `v-for`**
- Modifiers

Changing the option value

- For the 'gift' box, we don't want the customers to see `true` or `false`
 - But a message like 'Send as a gift' or 'Not send as a gift'
- This can be achieved by changing the return value of the select options with `v-bind:true-value` and `v-bind:false-value`.

```
<input type="checkbox" id="gift" value="true"  
  v-model="order.gift"  
  v-bind:true-value="order.sendGift"  
  v-bind:false-value="order.dontSendGift">
```

```
data: {  
  order: {  
    sendGift: 'Send as a gift',  
    dontSendGift: 'Do not send as a gift'  
  }  
}
```

The checkbox now returns the intended text.

Place Order

Value binding for the dropdown menu options

- Currently the options in the dropdown menu is hard coded.
- It will be better if we can read the list of states from `data` and generate the options dynamically.

```
<strong>State:</strong>
<select v-model="order.state">
  <option disabled value="">State</option>
  <option>AL</option>
  <option>AR</option>
  <option>CA</option>
  <option>NV</option>
</select>
```

Change the options with `v-bind`

- Just as the last example, we can change the options with `v-bind`
- Instead of `true` or `false`, the values are 'send as a gift' and 'do not send as a gift'
- Here we use `v-bind:value` instead of `v-bind:true-value` or `false-value`

```
<strong>State:</strong>
<select v-model="order.state" class="form-control">
  <option disabled value="">State</option>
  <option v-bind:value="states.AL">AL</option>
  <option v-bind:value="states.AR">AR</option>
  <option v-bind:value="states.CA">CA</option>
  <option v-bind:value="states.NV">NV</option>
</select>
```

The `states` array

- The `states` is an array in `data`
- Now the dropdown menu use the 'key's as options: 'AL', 'AR', etc.
- And returns the 'value': 'Alabama', 'Arizona', etc.

```
data: {  
  ...  
  states: {  
    AL: 'Alabama',  
    AR: 'Arizona',  
    CA: 'California',  
    NV: 'Nevada'  
  },  
}
```

State: CA ▼

Zip / Postal Code:

☒ Ship As Gift?

☒ Home ☐ Business

State: California

Gift? Send as a gift

Method: Home

Place Order

Using `v-for`

- With `v-for`, we can iterate through the array and generate the options dynamically,
 - Without having to list all the options in the dropdown menu

```
<select v-model="order.state">
  <option disabled value="">State</option>
  <option v-for="(state, key) in states"
    v-bind:value="state">
    {{key}}
  </option>
</select>
```

- In `v-for`, the `state` is an alias for element in the `states` array
- The `key` is an optional (but recommended) argument that specifies the index of the current item
- The `{{key}}` sets the key of `state` as the display for each dropdown option.

The generated HTML

```
<option value="Alabama">AL</option>
<option value="Alaska">AK</option>
<option value="Arizona">AR</option>
<option value="California">CA</option>
<option value="Nevada">NV</option>
```

- Now we can add all the states to the `states` array in `data`, and the dropdown selection options will be generated automatically.

v-for without the 'key'

- The 'key' in `v-for` is optional. The code below shows an example without it.

```
<div id="app">
  <ol>
    <li v-for="state in states">{{state}}</li>
  </ol>
</div>
<script src="https://unpkg.com/vue"></script>
<script type="text/javascript">
  var webstore = new Vue({
    el: '#app',
    data: {
      states: ['Alabama', 'Alaska', 'Arizona', 'California', 'Nevada']
    }
  })
</script>
```

1. Alabama
2. Alaska
3. Arizona
4. California
5. Nevada

Outline

- Binding values with `v-model`
- Binding values with `v-bind` and `v-for`
- **Modifiers**

The `.number` modifier

- The `.number` modifier changes the data type of `v-model` value to a number.
 - The default type is 'string' even if you add `type='number'`
- This can be used to convert the type of ZIP input into number
- `<input v-model.number="order.zip" type="number"/>`
- This can be checked with the `typeof` operator in the console

```
> 'before'
< "before"

> webstore.order.zip
< "1234"

> typeof(webstore.order.zip)
< "string"

> 'after'
< "after"

> webstore.order.zip
< 1234

> typeof(webstore.order.zip)
< "number"

>
```

Trimming the input values

- The `.trim` modifier can be used to remove white spaces before or after the text
- We will use this for the 'firstName' and 'lastName' in our form.
- `<input v-model.trim="order.firstName"/>`
- `<input v-model.trim="order.lastName"/>`
- Again we can check this in the browser console

```
> 'Before'
< "Before"

> webstore.order.firstName
< "    kai.    "

> webstore.order.lastName
< "    xu.    "

> 'after'
< "after"

> webstore.order.lastName
< "xu."

> webstore.order.firstName
< "kai."

> |
```
